Data Types		
byte	8 bits	0
short	16 bits	0
int	32 bits	0
long	64 bits	0L
boolean	bit	false
char	16 bit unicode	х
float	32 bit decimal	0.0f
double	64 bit decimal	0.0d

(='w')/

\(='w'=)/

```
byte[ -128 to 128 ][-2^{7} to 2^{7} -1] short[ -2^{15} to 2^{7}15-1] int[-2^{31} to 2^{7}15-1] long[-2^{63} to 2^{7}15-1]
```

Algorithm

```
An algorithm (pronounced AL-go-rith-um) is a procedure or formula for solving a problem.

Just like you have a recipe to cook food that has step-by-step instructions, in programming you have an algorithm that has step-by-step instructions.

Examples:

Sorting Algorithm

Swap Algorithm

Search Algorithm

Simple Algorithm to swap the values of two variables.

Examples:
```

Algorithm (cont)

```
int a = 4;
int b = 3;
int temp = a; //back up the value
of a
   a = b;
   b = temp;
Simple Algorithm to swap the values
of two items in a list.
Examples:
   public static void swap(int[]
list, int e1, int e2) {
      int temp = list[e1];
      list[e1] = list[e2];
      list[e2] = temp;
}
```

Decision Making

```
(if/else)
An if statement can be followed by
an optional else statement, which
executes when the Boolean
expression is false.
Examples:
if(Boolean_expression 1){
   //Executes when the Boolean
expression 1 is true
}else if(Boolean_expression 2){
   //Executes when the Boolean
expression 2 is true
}else if(Boolean_expression 3){
   //Executes when the Boolean
expression 3 is true
}else {
   //Executes when the none of the
above conditions is true.
(Switch)
A switch statement allows a
variable to be tested for equality
against a list of values. Each
value is called a case, and the
variable being switched on is
checked for each case.
```
